Aligning environmental management with ecosystem resilience: a First Foods example from the Confederated Tribes of the Umatilla Indian Reservation, Oregon, USA

*Eric J. Quaempts*¹, *Krista L. Jones*², *Scott J. O'Daniel*¹, *Timothy J. Beechie*³ and *Geoffrey C. Poole*^{4,5}

ABSTRACT. The concept of “reciprocity” between humans and other biota arises from the creation belief of the Confederated Tribes of the Umatilla Indian Reservation (CTUIR). The concept acknowledges a moral and practical obligation for humans and biota to care for and sustain one another, and arises from human gratitude and reverence for the contributions and sacrifices made by other biota to sustain human kind. Reciprocity has become a powerful organizing principle for the CTUIR Department of Natural Resources, fostering continuity across the actions and policies of environmental management programs at the CTUIR. Moreover, reciprocity is the foundation of the CTUIR “First Foods” management approach. We describe the cultural significance of First Foods, the First Foods management approach, a resulting management vision for resilient and functional river ecosystems, and subsequent shifts in management goals and planning among tribal environmental staff during the first decade of managing for First Foods. In presenting this management approach, we highlight how reciprocity has helped align human values and management goals with ecosystem resilience, yielding management decisions that benefit individuals and communities, indigenous and nonindigenous, as well as human and nonhuman. We further describe the broader applicability of reciprocity-based approaches to natural resource management.

Key Words: *Confederated Tribes of the Umatilla Indian Reservation; ecosystem resilience; First Foods; reciprocity; resilient rivers; tribal environmental management*

INTRODUCTION

Human communities depend on ecosystems for many services, such as drinking water, food, and building materials. One consequence of this dependence is ecosystem simplification as human actions tend to reduce the spatial and temporal complexity of ecosystems in order to maximize resource productivity and streamline management and harvesting actions. This simplification, in turn, can diminish ecosystem resilience. Resilience has many facets, including the capacity of an ecosystem to return to a reference state after a temporary disturbance (Grimm and Wissel 1997) and the amount of change that an ecosystem can absorb before governing processes shift, moving an ecosystem to an alternative stable state (Holling 1973). As resilience is diminished, ecosystems often lose their long-term viability and capacity to produce ecosystem services (Folke et al. 2010).

Environmental management strategies increasingly are focused on managing and restoring ecosystem resilience across landscapes where returning to predisturbance conditions is not a viable option (Folke et al. 2004, Chapin et al. 2010). Motivations include the ethical responsibilities of present-day generations to future generations and the need to manage for ecosystems that can withstand climate change (Waples et al. 2009, Anderson and Ferree 2010, Beier and Brost 2010, Chapin et al. 2011, Beechie et al. 2013). Managing for ecosystem resilience instead of short-term resource extraction involves a fundamental shift from managing ecosystems that are simple and static to managing ecosystems that

are complex and dynamic in space and time (sensu Peipoch et al. 2015) as well as adaptive learning and management (Gunderson 2000). Substantive questions remain as this management shift evolves. For instance, how can environmental management support resilient ecosystems, which in turn support the individual and societal needs of humans? What are the management approaches for balancing resilient ecosystems and resource use? How do environmental managers communicate management and restoration actions related to ecosystem resilience to their constituents? How do agencies shift to managing for ecosystem resilience and natural processes within an interagency context?

We offer the “First Foods” management approach of the Confederated Tribes of the Umatilla Indian Reservation (CTUIR) as a case study providing viable responses to such questions. The CTUIR Department of Natural Resources’s (DNR) First Foods approach has the following distinguishing components, which are described in detail below: (1) the explicit acknowledgement of reciprocity between humans and the environment as reinforced by the CTUIR’s creation belief and ritual serving order for culturally significant foods; (2) a departmental mission and structure organized by the First Foods approach; (3) the recognition and emphasis on the ecological ordering of First Foods; (4) the recognition of the spatial distribution of foods as modeled in the serving order, and (5) the identification of linkages between the serving order and the Walla Walla Treaty of 1855, thereby informing and enriching intergovernmental relations and collaborative opportunities. We

offer insights into how ecosystem resilience can be incorporated into environmental management strategies in ways that are meaningful to communities, helpful for interagency collaboration, and adaptable by other natural resource management entities. We describe the cultural basis of the First Foods, the CTUIR's use of resource visions to implement the First Foods management approach, and subsequent shifts in planning and goals among tribal environmental staff in their first decade of managing for First Foods. We also discuss how the First Foods approach may act as a lens for understanding natural resource stewardship in a way that resonates with people of diverse cultures and belief systems.

BACKGROUND

The Confederated Tribes of the Umatilla Indian Reservation

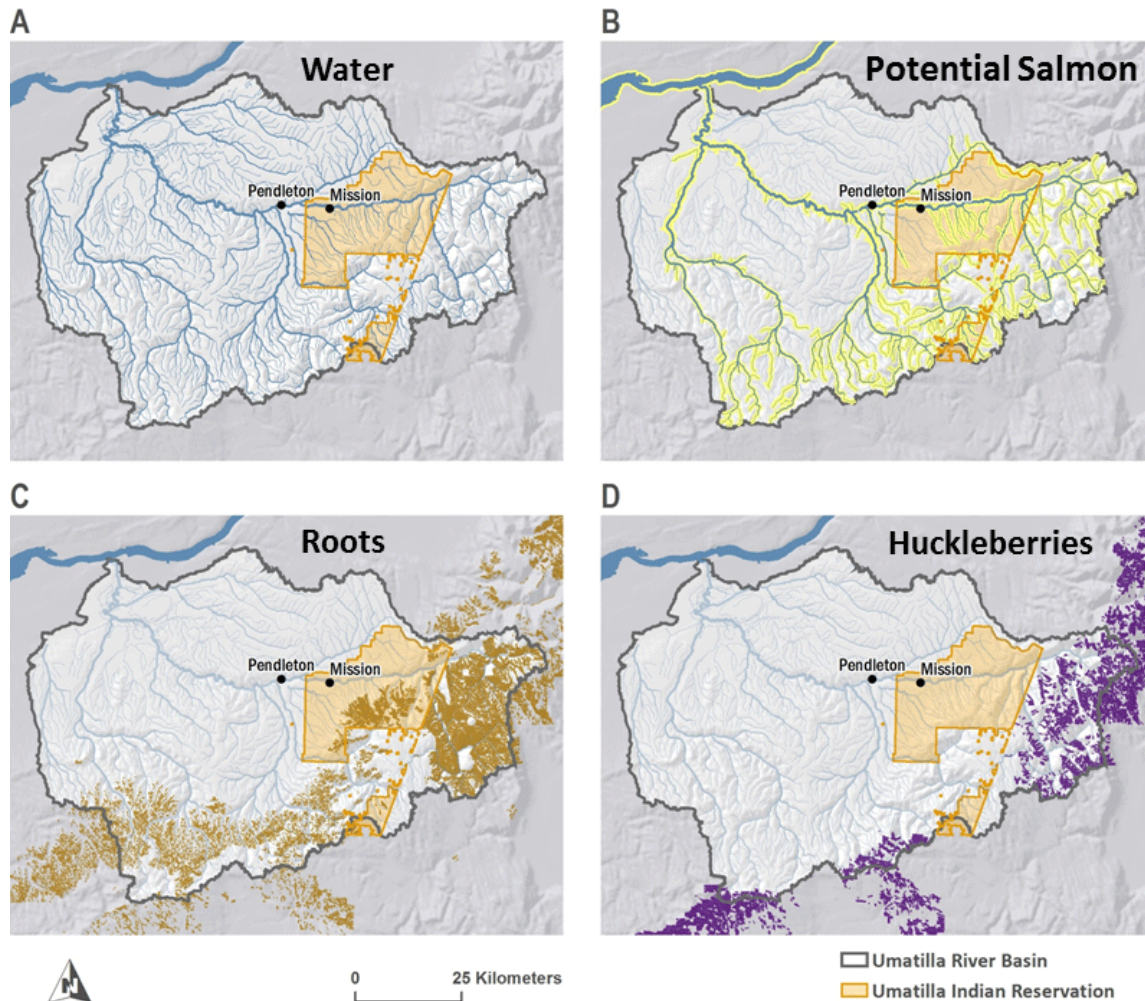

The CTUIR encompasses three tribal bands of confederacy, the Umatilla, Walla Walla, and Cayuse. The diminished Umatilla Indian Reservation (UIR) covers 6900 ha in northeastern Oregon (Fig. 1). The total CTUIR population was about 3075 members in 2016 (E. Lubrin, *personal communication*, CTUIR Enrollment Office, November 2016). About 4340 people, including CTUIR members, other tribal members, and nontribal members, resided on the UIR as of 2015–2016 (Umatilla-Morrow Counties Community Health Partnership 2016).

The CTUIR negotiated for the UIR and its ceded lands of 6.4 million acres (nearly 2,590,000 ha) in the Walla Walla Treaty of 1855 with the United States. On these ceded lands, the CTUIR retains rights to access and harvest treaty-reserved resources on open and unclaimed federal lands. Beyond these ceded lands is an extensive aboriginal use area that has been documented through oral histories and published literature (Hunn et al. 2015). The CTUIR manages for tribal natural resources and access to them on the UIR, ceded lands, and aboriginal use area through its own governance and intergovernmental relationships with local, state, and federal governments. The CTUIR actively collaborates with other natural resource agencies on lands outside the UIR because of tribal historical patterns of landscape use (Fig. 1), reserved Treaty rights, and the fact that lands within the diminished reservation boundary cannot provide the CTUIR with all First Foods (Fig. 2).

Cultural significance of First Foods

Food is integral to CTUIR ceremonies and traditions, as it is in other cultures, such as the feast of Thanksgiving in U.S. culture and the symbolic consumption of bread and wine in Christian ceremonies (The Holy Bible, Luke 22:19). At ceremonial feasts, the CTUIR people honor the five First Foods by serving them formally and before any other foods (Fig. 3). Four emblematic

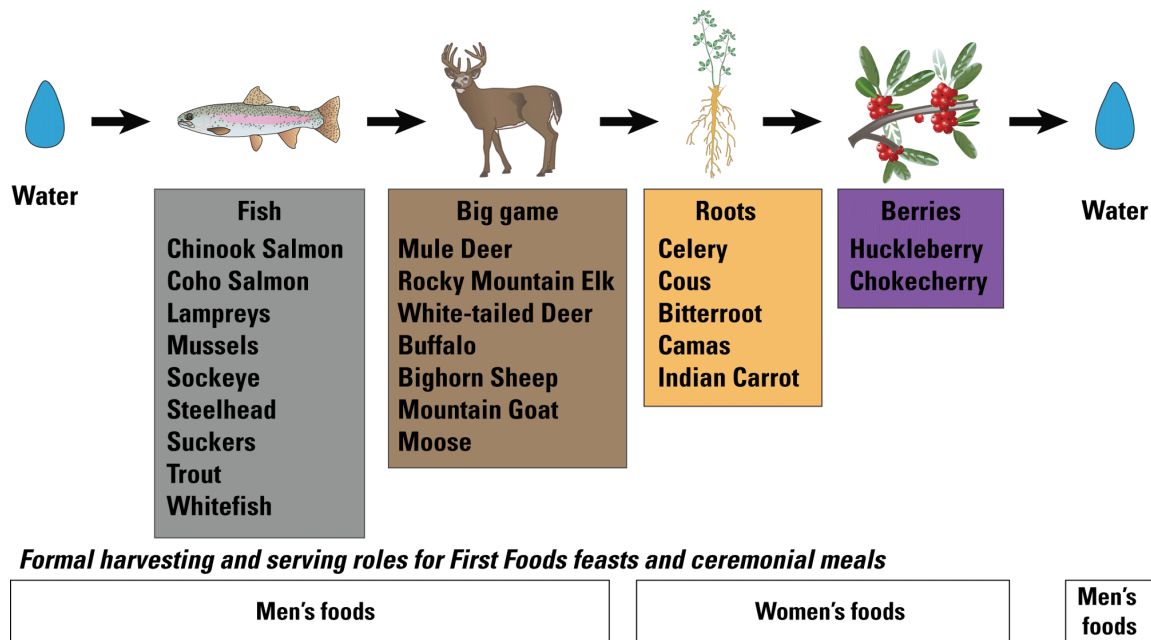

Fig. 2. Potential distributions of some First Foods of the Confederated Tribes of the Umatilla Indian Reservation, including: (A) Water: the stream network of the Umatilla River from the NHD Plus Version 2 (Horizon Systems 2013), (B) Salmon: the potential range of Pacific salmon (Confederated Tribes of the Umatilla Indian Reservation v. U.S. 1959), (C) Roots: modeled plant distributions associated with roots that serve as First Foods (Schumacher 2014), and (D) Berries: modeled plant distributions associated with huckleberries (Schumacher 2016).

First Foods, fish, big game, roots, and berries, are served in the order in which these foods promised to care for the Indian people according to the CTUIR creation belief (Relander 1986, Karson 2006, Confederated Umatilla Journal 2008). In the creation belief, “the Creator asked [of the creatures of the Earth], “Who will take care of the people?” Salmon said “I will” and the other fish lined up behind him, then the deer made a promise, and so on” (Confederated Umatilla Journal 2008). Water, the fifth First Food, is served before and after the four emblematic First Foods, in recognition of the fact that water is singularly essential, nourishing all other First Foods, people, and the landscape. Without water, none of the other First Foods can exist. The community celebrates First Foods when harvesting foods for feasts, everyday use after feasts, and honoring a tribal member’s first harvest of a First Food. They practice the serving order at funerals, memorials, naming of individuals, and weekly services

of the Washat, the religion of the Columbia Plateau tribes (Relander 1986). For First Foods feasts and other ceremonial meals, men serve the water and harvest and serve the fish and big game, while women harvest and serve the roots and berries (Fig. 3). These harvest gender roles may or may not be strictly followed during other times of the year, such as when harvesting for familial and personal use. The CTUIR community does not include any nontraditional foods in the First Foods serving order and ritual despite the introduction and abundance of new foods. For example, Smallmouth Bass (*Micropterus dolomieu*), a widespread introduced fish in the Pacific Northwest (Carey et al. 2011), is not used as a substitute for native fishes, nor wheat for roots. Instead, nonindigenous foods are served at ceremonies and feasts only after the ritual serving of First Foods, and without ceremony or significance. First Foods in these acts of ceremony and religion define and reinforce the identities of individuals, families, and the

Fig. 3. An example of the serving order of the Confederated Tribes of the Umatilla Indian Reservation. Foods are served in the order in which foods promised to care for the tribal people. This serving order includes some examples of culturally significant First Foods, but is not a comprehensive table setting. For First Foods feasts and other ceremonial meals, men harvest the fish and big game and serve the water, fish, and big game while women harvest and serve the roots and berries. These harvest gender roles are not strictly followed during other times of the year, such as when harvesting for familial and personal use. tribal community (sensu Holtzman 2006), and signify the enduring linkages between the CTUIR people and their food, values, and environment.

The CTUIR's creation belief also reinforces "reciprocity" between First Foods and the CTUIR people, meaning First Foods promised to care for the people and the people are responsible for the care and protection of First Foods. Since time immemorial, the CTUIR has benefited from First Foods used for subsistence, ceremony, and medicine. Tribal members benefit from the nutrition and exercise associated with traditional practices and access to traditional resources (Kuhnlein and Receveur 1996, Cochran and Geller 2002, Hess et al. 2008). Data on the proportion of First Foods in the CTUIR's diet are unavailable; however, steady participation at feasts, regular use of First Foods for subsistence by tribal members, and increasing awareness of the health benefits of a traditional diet reflect the dietary importance of First Foods to the CTUIR. In turn, the CTUIR people take care of First Foods through actions that support resilient ecosystems and First Foods. For instance, root-harvesting practices include leaving most roots to complete their life cycle at harvesting sites, replanting the flowering heads of harvested roots for continued production, or postponing harvest until seeds have dropped. Similarly, individuals leave some berries on huckleberry bushes for forage by bears and other animals and to encourage continued berry production. Such explicit, intentional, and enduring actions emphasize and prioritize

ecosystem resiliency over short-term maximization of resource extraction. Moreover, these expressions of reciprocity reflect a recent shift in CTUIR individual and community actions from solely supporting concepts of western culture, such as "sustainability," toward reembracing the traditional concepts of supporting and sustaining First Foods and their cultural, religious, and subsistence significance in honor of the promises made by the First Foods to care for the CTUIR people.

Diminishment of First Foods

From time immemorial to Euro-American settlement and the Walla Walla Treaty of 1855, dynamic natural processes and tribal practices maintained plentiful First Foods (Fig. 4). Water from melting snow pack fed the rivers, connecting them seasonally with their floodplains. Fires ignited by thunderstorms reset terrestrial vegetation communities, and helped supply rivers with new spawning gravels for salmon and lamprey. Big game First Foods, such as mule deer (*Odocoileus hemionus*), elk (*Cervus canadensis*), and bighorn sheep (*Ovis canadensis*; Fig. 3) migrated across the landscape unencumbered by fences and other artificial barriers. Meanwhile, the CTUIR, like other tribes in the Pacific Northwest, used fire to manage huckleberry fruit production (Minore 1972, Fisher 1997) and create foraging areas for big game. They harvested foods across the dynamic landscape in synchrony with plant phenology and food availability. The arrival of horses on tribal lands in 1770 increased tribal access to all First Foods because they helped the CTUIR tribal members expand their range for hunting and harvesting (Figs. 1, 4).

Fig. 4. Timeline of representative events benefiting or diminishing First Foods and tribal access to them, time immemorial to 1913.

Accessibility and abundance of First Foods began to decline for the CTUIR with Euro-American settlement and later substantial reductions in the area of the UIR. The UIR was reduced from over 99,000 ha to about 64,000 ha over the course of four reductions from 1885 to 1888 (Fig. 4). Resource use by the expanding non-native human population increasingly was dominated by extractive and intensive management approaches, rather than by a culture of reciprocity and support of resilient ecosystems. For example, Euro-American management has included the extraction of mineral and water resources and intensive management of agricultural lands for single crops; such management focuses on the production of a limited number of resources at the expense of numerous others and on controlling natural processes that create habitat and biological diversity across the landscape. As a result, the physical, biological, and ecological processes that support First Foods have been impaired by many changes, such as dams, floodplain simplification, fire suppression, water extraction, pollution, grazing, deforestation, commercial and irrigated agriculture, crop introductions, and placer and gravel mining. These changes along with Euro-American suppression of CTUIR natural resource management, cultural expressions, and religious practices contributed to the simplification of native ecosystems and the eventual decline of many culturally important resources (Figs. 4-6).

In this modern landscape, many First Foods, such as salmon, lampreys, and mussels, have declined precipitously (Gresh et al. 2000). For example, over 10–16 million salmon and steelhead (*Oncorhynchus* spp.) returned to the Columbia River historically; these runs declined to 5–8 million (a 50% loss) from the 1800s to the 1930s because of overharvest and habitat degradation, and then declined further to 1–2 million (a 90% loss) since the construction of the mainstem Columbia River dams (Montgomery 2003; Figs. 5-7). As early as 1926, the Oregon Department of Fish and Wildlife found no Chinook (*Oncorhynchus tshawytscha*) or Coho (*O. kisutch*) salmon in the Umatilla River (Boyce 1986; Fig. 5). Multiple salmonid Evolutionary Species Units (ESUs) were listed as “Endangered” or “Threatened” under the Endangered Species Act (ESA) from 1991 to 1999 and Pacific Lamprey (*Entosphenus tridentatus*) were petitioned for listing in 2003 (Figs. 7, 8). Today, the salmonids remain listed under the ESA (Fig. 9). In addition, Pacific lamprey numbers remain low in the Umatilla basin, requiring the CTUIR to travel more than 360 km to collect Pacific Lamprey at Willamette Falls near Portland, Oregon. Other First Foods, such as huckleberries (*Vaccinium* spp.), are commercially harvested by nontribal individuals from federal lands in manners that threaten their availability to tribal members (Minore et al. 1979).

CTUIR NATURAL RESOURCE MANAGEMENT

Prior to the creation of the CTUIR’s Department of Natural Resources, the abundance and availability of First Foods were conserved by Supreme Court rulings, the Clean Water Act, the ESA, and the collective scientific, habitat restoration, and policy actions of the CTUIR (Figs. 5-8). For example, the Supreme Court case *U.S. v. Winans* (1905) established that tribes retained sovereignty and reserved rights to continue their ways of life through the treaty negotiations and that the U.S. has federal trust responsibility to the tribes (Blumm and Swift 1998, Pevar 2012). This means that the CTUIR retained their rights to the access and use of usual and accustomed places and reservation lands as

identified and negotiated in the Walla Walla Treaty of 1855 (Figs. 1, 4). The CTUIR also shares governance of natural resources with federal and state agencies, resulting from the treaty making process outlined in Article VI of the U.S. Constitution. For example, several federal departments, such as the Interior, Agriculture, Commerce, and Defense, are responsible for consulting with tribes on the management of federal actions that might affect tribal natural resources associated with the treaties between tribes and the U.S. Federal Government (Galanda 2011), and developing consultation policies focused on tribes (Executive Order No. 13175). The resulting government-to-government relationship enables tribes and the federal government to have discussions on issues of concern, including the management of resources important to tribal culture.

Within the CTUIR, governance for natural resources starts with the Board of Trustees (BOT). The BOT is a group of nine people elected by the General Council to protect the CTUIR rights as reserved in the Walla Walla Treaty of 1855, set policy, make final decisions on tribal affairs, and determine priority projects and issues on behalf of the CTUIR and residents of the UIR. The BOT formed the DNR in 1982 to manage resources on the reservation and, in collaboration with state and federal agencies, on ceded lands and in aboriginal use area (Fig. 1). The original mission of the DNR was to “... protect, enhance and restore the natural and cultural heritage of the CTUIR by ensuring the long-term health, availability, wise-use, and production of the tribe’s natural and cultural resources in a manner consistent with Tribal values and scientifically sound resource management” (CTUIR 2005:2). In 2005, the DNR consisted of six programs: Administration, Cultural Resources Protection, Water Resources, Fisheries, Wildlife, and Environmental Planning and Rights Protection Programs. The DNR has grown substantially in terms of staff, number of projects, budgets, and number of cooperating agencies from 1995 to 2015 (Table 1).

Table 1. Staffing, number of projects, and number of cooperating agencies for the Department of Natural Resources for the Confederated Tribes of the Umatilla Indian Reservation, 1995 to 2015.

Years	Number of employees	Number of projects	Number of cooperating agencies
1995–1999	80	78	13
2000–2004	85	143	34
2005–2010	109	174	42
2011–2015	127	186	43

CTUIR DNR efforts, 1982 to 2005

The DNR faced many challenges in its first 23 years of managing for natural resources. The main challenge, then and today, is securing CTUIR water rights for instream flows and consumptive uses to meet the needs of the UIR community and fulfill the purpose of the UIR as the CTUIR’s homeland. As of 2018, these water rights have not been secured, and the CTUIR is actively working with a federal negotiation team to permanently protect water, for both instream and consumptive uses. The process of securing rights has been ongoing since the 1980s and the passage

of the federal Umatilla Basin Project Act (U.S.C. Public Law 100-557) in 1988 (henceforth, UPB Act; Figs. 7-9).

A second challenge faced by the CTUIR DNR from 1982 to 2005 was the limited CTUIR governance capacity. This limited capacity restricted the scope of activities that the CTUIR was able to undertake and prevented them from pursuing multiple complex efforts simultaneously. This capacity has increased over time (Table 1; Figs. 7-8)

A third challenge faced by the CTUIR DNR from 1982 to 2005 was re-establishing extirpated salmon and lamprey in the mainstem Umatilla River through artificial propagation and fish supplementation programs (Figs. 7-8). The UPB Act helped provide some incremental progress toward improving base flows and fisheries in the Umatilla River because it allowed Umatilla Basin agricultural irrigators to use water instead from the Columbia River, leaving water in the Umatilla River during summer to support the artificial salmonid supplementation programs from 1993 to 1999 (Phillips et al. 2000, Shelley 2002). The UPB Act implementation required that the CTUIR DNR collaborate with the Oregon Department of Fish and Wildlife (ODFW), Bonneville Power Administration (BPA), the U.S. Bureau of Reclamation (BOR), Oregon Water Resources Department (OWRD), and the Hermiston, Stanfield, West Extension, and Westland Irrigation Districts. DNR staff operated fish supplementation facilities, and released spring and fall Chinook and Coho salmon (in 1982), Pacific lamprey (in 2000), and mussels (*Bivalvia*: *Unionoida*; in 2005) to initiate reintroduction in the Umatilla basin. Staff observed the first returns of reintroduced spring and fall Chinook and Coho salmon from 1984 to 1989, resulting in the CTUIR's Umatilla basin salmon return celebration in 1984 and the re-establishment of tribal salmon fishing in the Umatilla River in 1990 (Figs. 7-8). Positive outcomes of the UPB Act included the subsequent fishery and improved summer flows in the Umatilla River. The UPB Act also spurred the CTUIR to establish goals for salmon restoration, and enabled the CTUIR to take a coequal role in government-to-government dialogues concerning natural resource issues. Irrigators, state water managers, local governments, and other cooperators recognized that the restoration of salmon to the Umatilla River would have been unlikely without the involvement, initiative, and persistence of the CTUIR DNR (Shelley 2002). Today, much work remains to continue to build on these successes in the lower Umatilla River basin where water quality, fish productivity, and habitat continue to persist at greatly suppressed levels of ecological function (Miller et al. 2007).

CTUIR DNR's First Foods management approach and mission, 2006–ongoing

Addressing the complex and inter-related challenges faced by the CTUIR DNR from 1982 to 2005 and responding to the CTUIR community's calls for management of all First Foods required that the CTUIR DNR adopt a more holistic and coherent approach, make the argument for increased organizational capacity, and prioritize management actions to meet community needs. Thus, in 2006, the "First Foods Management Approach and Mission" were introduced to DNR staff as a means of organizing DNR work goals and efforts in response to community cultural values and practices. Staff then reviewed the draft mission quarterly and multiple times with commissions, committees, and

the BOT. Later that year, DNR proposed that the mission serve as the guiding element of the DNR's annual work plan. The BOT approved the adoption of the mission and its implementation, starting 1 January 2007, as follows:

To protect, restore, and enhance the First Foods - water, salmon, deer, cou, and huckleberry - for the perpetual cultural, economic, and sovereign benefit of the CTUIR. We will accomplish this utilizing traditional ecological and cultural knowledge and science to inform: 1) population and habitat management goals and actions; and 2) natural resource policies and regulatory mechanisms. (CTUIR 2006:2)

This mission statement is a community-driven management response to the incapacity of the present-day local landscape and UIR to support the full table setting for ceremony and subsistence uses (Fig. 2).

In 2007, the DNR was reorganized into five programs that relate directly to the major divisions in the First Foods serving order (Fig.3): Water - Water Resources Program, Fish - Fisheries Program, Big Game - Wildlife Program, Roots - Range Program, and Berries - Forestry Program. Three other DNR programs (Cultural Resources Protection Program, Outreach and Educations Specialist, and First Foods Policy Program) supports all foods in their work. The DNR now has about 127 staff, reflecting the department's growing capacity (Table 1). The inclusion of the First Foods in the DNR's mission statement also provides guidance to tribal programs that assist in the planning and implementation of DNR efforts, such as the Geographic Information Systems program and Office of Legal Counsel. For the CTUIR DNR and other programs, the First Foods management approach and mission provide a coherent management and governance structure that is responsive to community requests for these resources and the order in which the First Foods are harvested and served.

In the first 10 years of implementing the First Foods management approach and mission, the DNR has emphasized the collective First Foods serving order over individual First Foods. The rationale is that doing so increases management responsiveness to the community, provides a direct connection with the promises made by all foods in the tribal creation belief, and reflects the phenology and geographic distribution of the foods in the serving order. For example, the seasonal progression of available foods follows an elevation gradient, beginning in the spring along the Columbia River, progressing into the mountains during the summer, and returning to the tributaries, like the Umatilla River, in the fall. The First Foods management approach has extended management efforts to encompass big game, roots, and berries and the full First Foods table setting more explicitly (Fig. 3). Big game efforts have included coordinating tribal harvest opportunities, such as the hunting of sensitive populations of bighorn sheep and mountain goats with ODFW and buffalo hunts with the Montana Fish, Wildlife, and Parks in 2009 because buffalo are unavailable for hunting on UIR (Figs. 8, 9). Root and berry efforts have included developing a traditional use report for huckleberry (Schumacher 2016) and mapping distributions of five root foods on 15,284 ha with United States Department of Agriculture Forest Service (USFS) in 2008 and another three root foods on an additional 52,768 ha with the Bureau of Land

Management (BLM) in 2009. Root and berry efforts have also focused on coordinating tribal access for harvesting. For example, the DNR secured access through a Memorandum of Agreement (MOA) with a private energy developer for root digging access on isolated BLM parcels starting in 2007.

EMERGING INSIGHTS FROM THE CTUIR'S FIRST DECADE OF IMPLEMENTING THE FIRST FOODS MANAGEMENT APPROACH

Over the last 10 years, the DNR has gained insights into the First Foods approach and the ways in which it has benefited their management of culturally significant natural resources. Here, we provide examples of some benefits that may be meaningful to other tribal managers and, in some cases, nontribal managers.

“Visionary” management that integrates science to support natural resource management and ecosystem resiliency

The First Foods management approach and mission reflect an overarching management goal for the DNR that would help fulfill community requests for First Foods. However, they do not outline the scientific considerations and context necessary for restoring, protecting, and enhancing First Foods on and off the reservation. Thus, early in implementing the First Foods approach, the DNR identified the need for culturally consistent, management visions that were rooted in scientific knowledge to help “tribal and nontribal managers in moving the First Foods mission from concept to application” (Jones et al. 2008a:ii). Such visions can be helpful frameworks for planning management and restoration efforts, assessing success or failure, and considering specific management and restoration actions within the context of other actions (Jungwirth et al. 2002). To date, the CTUIR has developed the River Vision for water and salmon (Jones et al. 2008a), and is developing a complementary vision for the uplands that will encompass big game, roots, and berries. Common elements of the River Vision and forthcoming Uplands Vision are overviews of the critical processes and interactions supporting functional ecosystems and First Foods, ecosystem impairments, and some key challenges and questions for the management and restoration of First Foods. Here, we discuss the River Vision in more detail to illustrate how it connects First Foods, ecological and physical processes, and habitat restoration, and aids the DNR in its mission to protect and restore riverine First Foods.

The River Vision was the first CTUIR management vision developed in 2008, owing to staff capacity, the agency’s emphasis on water and fisheries to date, and available resources. It described the management vision for rivers, water, and associated First Foods, such as salmon, trout, lamprey, whitefish, suckers, and mussels (Fig. 3). It summarized the interactions between five components (or “touchstones”), hydrology, geomorphology, connectivity, riparian vegetation, and aquatic biota, that shape resilient and functional rivers. It synthesized research done on the Umatilla River by DNR staff in collaboration with university scientists. This research highlighted how interactions between streamflow and geomorphic processes influence water exchange between the river channel and its alluvial aquifer (termed “hyporheic exchange”), thereby helping to buffer stream temperatures (Arrigoni et al. 2008, Jones et al. 2008b,c, Poole et al. 2008). Some outcomes of these hydrologic and geomorphic processes include thermal variability, habitat diversity, and upwelling hyporheic sites where salmon preferentially spawn

(Baxter and Hauer 2000, Geist et al. 2002). The River Vision explains the scientific underpinning of these processes and their relationships with riverine First Foods so that the CTUIR DNR has a solid scientific foundation for implementing First Foods management.

The River Vision also identifies potential hurdles to the First Foods mission related to water and fishes. In particular, the River Vision emphasizes the need for process-based restoration to address the causes of river ecosystem degradation (Kondolf et al. 2006, Beechie et al. 2010). Process-based restoration focuses on allowing hydrologic and geomorphic regimes to shape river corridors at spatial scales that match the spatial scale of problems attempting to be addressed through restoration (Poff et al. 1997, Roni et al. 2002, Beechie et al. 2010). Accordingly, the CTUIR DNR Fisheries Habitat Program has shifted from implementing site-scale projects (involving 10s to 100s of m of stream channel) to reach-scale projects (1000s of m in length) to improve habitat for listed salmonids and other riverine First Foods. This shift reflects the new understanding, shaped by the First Foods approach and River Vision, that successful habitat restoration must address larger scale processes that create habitat features suitable for salmonids, other native fishes, and mussels.

DNR staff has applied the processes and science synthesized in the River Vision to their implementation and monitoring of habitat restoration projects (Figs. 10, 11). One example of this new approach is the DNR’s restoration of 2.6 kilometers along Meacham Creek, Oregon (Fig. 10), with the goals of improving salmonid habitat and restoring geomorphic processes and hyporheic exchange. Prior to restoration, Meacham Creek had been repeatedly rerouted away from the Union Pacific Railroad from 1890 to 2000 with a series of dikes and channel-straightening efforts (Andrus and Middel 2003). As a result, Meacham Creek lacked complex instream habitats, and was too warm for spring Chinook salmon, bull trout (*Salvelinus confluentus*), and summer steelhead (Richter and Kolmes 2005). The expressed purpose of the Meacham Creek restoration project was to restore hyporheic exchange in order to improve stream temperatures (CTUIR 2012). To accomplish this goal, the DNR, Bonneville Power Administration (BPA), and USFS did not rely on creating channel meanders (sensu Kondolf 2006), pools, or other structural habitat components. Instead, they moved the straightened channel, which had been dredged to bedrock, from the floodplain margin back to its historical position at the center of the floodplain, atop alluvial gravels. They also avoided the use of bank hardening structures that would prevent channel migration, and gave the channel room to move across its floodplain via active and dynamic geomorphic processes, such as avulsion, bank erosion, and sediment accretion, in response to high flow events over time. This restoration approach is consistent with the premises of process-based restoration, and allows the channel to be shaped by active hydrologic and geomorphic processes over time. Following restoration, surface waters in Meacham Creek now inundate the floodplain during flood events, and rework the floodplain and stream channel (Fig. 10). Re-establishing this interplay between hydrologic and geomorphic processes is a key part of restoring this gravel-bedded river and creating a geomorphic template that supports hyporheic exchange (Arrigoni et al. 2008, Poole et al. 2008, Hester and Gooseff 2010), improves water quality (Poole et al. 2004), and improves habitat conditions for salmonids and

Fig. 10. Images of a portion of the Meacham Creek habitat restoration site: (A) Before restoration (8 June 2005), (B) Immediately after restoration (10 August 2012), and (C) Four years post restoration (3 June 2016). Images are from Google Earth.

other riverine First Foods (Waples et al. 2009, Bellmore et al. 2013).

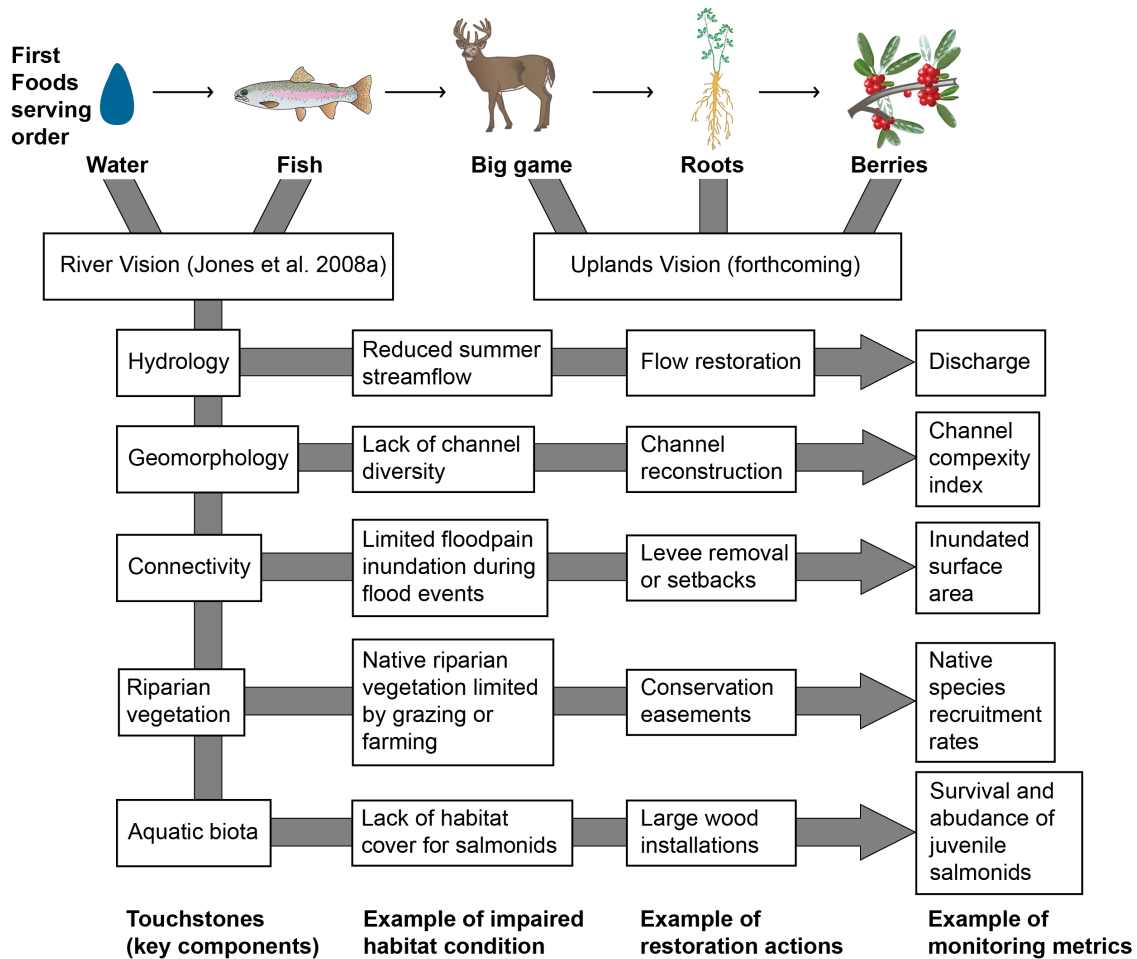

In sum, the River Vision provides a scientifically based, implementation road map for the First Foods management approach related to water and fishes. It acknowledges that First Foods themselves will be resilient to change when the touchstones and processes creating aquatic and floodplain habitats are intact (Jones et al. 2008a). The River Vision's scientific framework has helped DNR managers and staff identify the necessary touchstones for resilient ecosystems, pinpoint any adverse changes in these components, and implement daily and long-term mitigation and restoration actions in support of First Foods as illustrated by the Meacham Creek restoration project. It also helped DNR staff working on different river conservation and

restoration objectives, such as water quality or salmon spawning habitats, to coordinate their management actions and planning efforts. Without the scientific roadmap of the River Vision, DNR staff would not have an explicit way of linking First Foods with ecological and physical processes, science, and habitat restoration approaches, nor would they have the scientific foundation for communicating their goals and objectives to the tribal community as well as federal, state, and local collaborators.

Increased management of other natural resources

Another tangible outcome of the First Foods mission was that it helped the DNR extend their management efforts beyond water, salmon, and other fishes to encompass big game, roots, and berries (Fig. 3). This was a fundamental shift in the agency's management in response to community requests' to protect the women's foods,

Fig. 11. Linkages between First Foods, resource management visions, and management and habitat restoration actions. This figure focuses on the relationships between the River Vision, touchstones (or key components) of riverine ecosystems that support First Foods, and restoration actions and monitoring metrics related to addressing and measuring progress toward improving impaired habitat conditions. roots and berries, and access to them. Historically, the CTUIR did not have the management capacity to focus on these foods; as a result, the abundance of these foods and tribal access to them diminished over time. Since the adoption of the First Food approach and mission, the CTUIR governance and DNR have assessed the amount, distribution, and accessibility of these foods and developed responsive management actions. By explicitly addressing the entire First Foods serving order (Fig. 3), the DNR is being responsive to the values of all community food gatherers, helping to increase the community's understanding of the distribution and availability of foods, and focusing management attention and resources on the habitat needs of all foods and related tribal access. Proactive management of the full serving order increases the likelihood that food abundance and food access will meet community requirements and contribute to cultural continuity.

Building interagency collaboration for the comanagement of natural resources

The DNR actively works to manage natural resources on and off the reservation in collaboration with tribal, federal, state, and local agencies because the diminished reservation cannot provide the CTUIR community with an adequate supply of all First Foods (Fig. 2). In doing so, the DNR has found the First Foods approach and related management visions beneficial because they help communicate the cultural significance of First Foods to the CTUIR community, identify key processes supporting the First Foods, and assist DNR and nonindigenous agencies in identifying collaboration opportunities. The DNR's work on riverine First Foods with the River Vision provides the best illustrations of these points. The DNR works with at least seven federal agencies, five state agencies, and multiple local county and zoning agencies in their effort to improve and sustain water and fishes. These projects represent new and novel types of agreements between the CTUIR

and cooperating agencies that are aided by the structure of the First Foods approach. In these collaborations, First Foods serve as focal points (or boundary objects, *sensu* Clark et al. 2011, Robinson and Wallington 2012), which enable the CTUIR to share the cultural significance of First Foods and have meaningful conversations with cooperating agencies. The scientific understanding of physical and ecological processes summarized in the River Vision has helped the DNR communicate the importance of critical ecological and physical processes that support First Foods, and helped other agencies to identify processes that are relevant to First Foods and within their mission areas. With this common ground, the DNR has built successful collaborations with other tribal and nontribal agencies to manage and restore resilient riverine ecosystems and First Foods.

The structure provided by the First Foods approach has also been helpful as the DNR establishes new state and federal cogovernance relationships to manage big game, roots, and berries. On the UIR, CTUIR DNR assumed the management responsibilities for the BIA Range and Agriculture Programs in 2008 and BIA Forestry Program in 2010. Since then, the CTUIR DNR has incorporated big game, roots, and berries into their management of grazing, farming, and forestry activities. The management directives for the prior BIA programs did not include or address First Foods, and focused on trust landowners receiving fair market value for extracted resources, such as timber harvest, grazing, and gravel. Further from the UIR, the CTUIR DNR successfully negotiated the re-establishment of tribal buffalo hunting in Montana with the Montana Fish, Wildlife, and Parks in 2009 (Fig. 8). This negotiation was supported by a CTUIR Cultural Resources Protection Program (2009) report, which documented the importance of buffalo as a traditional First Food to the CTUIR people using oral histories and outlined treaty protected rights for natural resource access and use within the context of the Walla Walla Treaty of 1855. The buffalo hunting agreement has significant implications for the CTUIR's treaty-protected rights to collect First Foods outside of previously defined areas and the UIR, because it provides a road map for CTUIR to use their research and First Foods management approach to help negotiate the re-establishment of traditional practices and harvesting opportunities.

Culturally meaningful reporting units

Adoption and implementation of the First Foods approach have given the DNR a culturally appropriate means of reporting the benefits associated with habitat restoration and other natural resource management actions to their community. This shifts the focus from reporting units that are disconnected from tribal culture to First Foods reporting units that reflect the values, traditions, and religion of the CTUIR community as well as dynamic and resilient ecosystem processes. In turn, the CTUIR community directly observes the diversity, regularity, and quality of First Foods that are available for feasts and everyday use. The CTUIR community can provide feedback on DNR efforts through community open houses, General Council meetings, and regulatory commission meetings. The DNR can then use the community-expressed needs and goals to inform work planning for research, assessments, and restoration plans that are reviewed and approved by tribal policy makers.

Transferability to other tribal and indigenous managers

The First Foods management approach is most directly transferable to other tribes and indigenous groups where community values and management goals are broadly shared and aligned with ecosystem resilience. Therefore, the DNR has helped convene workshops on traditional foods management, and presented and shared the First Foods with other indigenous groups (Fig. 9). Sharing successful strategies for indigenous and nonindigenous collaborations is important because some indigenous communities are reticent to share information on cultural significant resources because of fear of continued or increased exploitation of foods and resources that are sacred to them. For example, Pacific Northwest tribes have seen water overdeveloped and polluted, fish communities driven to extinction or endangered status, conflicts over big game harvest, and commercial exploitation of huckleberry and other First Foods. Understandably, some indigenous communities are reluctant to share data on the distributions of foods and resources with nonindigenous agencies and individuals. Nonetheless, an indigenous community's readiness and willingness to share information about its culturally significant foods and resources directly affects their ability to apply the First Foods management approach and collaborate with nonindigenous agencies.

Indigenous agencies can take steps to protect their resources when sharing sensitive information on culturally significant foods and resources and building collaborative relationships with nonindigenous agencies and individuals. In managing for First Foods with nontribal agencies and individuals, the DNR has used governance tools, such as policies, memoranda of understanding or agreement, and data sharing agreements that limit the specificity with which collaborating agencies can display or distribute information on culturally significant foods and resources. For example, the CTUIR has signed data sharing agreements with BLM and USFS for the women's food mapping projects and MOAs for access and harvesting on private properties. These types of governance tools and other guidelines have been shared with other indigenous communities by the Climate and Traditional Knowledges Workgroup to help protect ecological and traditional knowledge about species, harvesting locations, and traditional uses when sharing these types of data with nonindigenous partners (Climate and Traditional Knowledges Workgroup 2014). Other resources that discuss protecting traditional knowledge include Davis and Reid (1999), Lomawaima (2000) and Fisher and Ball (2003).

More broadly, because the First Foods approach as a strategy has assisted the CTUIR in maintaining and supporting its cultural values as expressed through the tribal creation belief, First Foods serving order (Fig. 3), and associated practices, we suggest the First Foods approach may offer similar benefits to other indigenous communities. The resurgence and re-expression of CTUIR tribal values through First Foods is evidence of the resilience and tenacity of tribal culture (*sensu* Rotarangi and Stephenson 2014). This adaptation strategy for tribal natural resource management aligns management goals with tribal community requests first and foremost, while also providing a path forward for building collaborations with nontribal agencies. Given that other indigenous communities have similarly experienced suppression of their natural resources, resource management, culture, and religious practices by Euro-American

society, using a First Foods management approach, that is uniquely adapted to their culturally significant foods, ecosystems, and landscapes, may benefit their cultural resilience while also making their values and goals accessible to nonindigenous agencies and public.

Communication with the nontribal public

We end this overview of the CTUIR's First Foods approach with a reflection on communicating the cultural significance and management of First Foods with nontribal individuals. To date, staff from the CTUIR DNR has presented the First Foods approach over 100 times to other tribes and indigenous communities, state and federal agencies, local governments, universities, professional societies, and nongovernmental organizations. Staff has also shared the CTUIR's First Foods culture and management approach with over 18,200 K-12 public school students and over 12,000 adults at outreach and education events, primarily in northeastern Oregon and southeastern Washington, from 2008 to 2016. Informal feedback on these presentations received by the principal author, Eric Quempt, indicates that three main messages resonate with the nontribal public. These messages may help nontribal individuals to consider First Foods, physical and ecological processes, and reciprocity in their own lives and to support the management, protection, and restoration of First Foods and ecosystem resilience.

The first message is that the First Foods approach aids people in making more personal and direct connections to the environment, through a shared understanding of the importance of food and food rituals, as it relates humans to functional and resilient ecosystems. This is probably because individuals from dissimilar backgrounds often share the collective human experience of certain foods symbolizing their family or community traditions (sensu Holtzman 2006). The second message is that the ecological groupings of foods (Fig. 3) and the spatial distribution of the serving order across the landscape (Fig. 2) underscore the importance of ecology and phenology and the need for functional landscapes encompassing rivers and floodplains up to the mountaintops. This is in alignment with our scientific understanding of ecosystems and the processes that sustain them. The third message is that individuals connect with the theme of reciprocity between the tribal community and First Foods. Reciprocity is an elegant connection between humans, foods, and landscapes that is an integral belief in many tribal and indigenous communities. Reciprocity counts human actions as an integral part of natural processes where a shared dependence is essential to the survival of both people and all other organisms. The importance of reciprocity may be reminiscent of the land ethic of Aldo Leopold (1970) to nonindigenous individuals with different belief systems, and may assist in making the cultural significance of managing and restoring First Foods more transferable to other individuals and communities. Further, unlike the concept of environmental sustainability where actions are summed to continental and global scales (Goodland 1995), the concept of reciprocity is inherently place based and bound by human harvest interactions across a landscape. Although a detailed discussion is outside the scope of this paper, we surmise that reciprocity may be a useful alternative to prevailing environmental concepts, such as sustainability, for connecting individuals with place, natural resource management, and habitat restoration. This is because reciprocity resonates on a personal

level with individuals from different backgrounds and belief systems (sensu Ryan 2014). The applicability and effectiveness of reciprocity, as experienced by the CTUIR in the implementation of the First Foods approach, are worthy of more explicit consideration and inclusion by the environmental management and restoration community.

CONCLUSION

The CTUIR developed the First Foods management approach to be responsive to the community's requests for restored, sustainable, and accessible First Foods. Over the last 10 years, the First Foods approach has helped the DNR expand their efforts to include the entire First Foods serving order (Fig. 3). In applying this approach, the DNR emphasizes the reciprocal relationships between natural resources and humans. This is a deeply held and widely shared belief within the tribal community that means humans are responsible for taking care of the foods that provide sustenance to humans. This relationship is expressed in the concept of "reciprocity" between the community and the environment. Furthermore, the First Foods management approach provides the Tribal community with a means to "monitor" the performance of its government as the diversity, quality, and regularity of First Foods that can be harvested, served, and safely consumed are direct and meaningful indicators of the DNR's management effort and progress.

The First Foods management approach has improved intergovernmental and interagency understanding and collaboration for three reasons. First, through food, it relates humans to functional and resilient ecosystems, and assists people in making more personal and direct connections to the environment. Second, it provides cultural, ecological, and spatial frameworks for research and applied management and restoration. Third, it provides a means for communicating indigenous community values and goals to nonindigenous agencies and individuals. The transferability of the First Foods management to other indigenous managers is high where other indigenous communities are willing to safely share information about culturally significant foods and resources. Nonindigenous governments and management agencies can interact with First Foods management via the ecological and spatial relationships inherent in the First Foods serving order. They can also use this framework to improve their understanding of indigenous community goals, identify areas of management overlap and collaborative potential, and find ways to assist indigenous groups in caring for the foods and ecosystems that care for us all.

Acknowledgments:

We thank the community of the Confederated Tribes of the Umatilla Reservation (CTUIR) and staff of the CTUIR Department of Natural Resources (DNR) for their inspiration and efforts related to celebrating, recovering, and managing First Foods. We thank Jim Webster for his insights into the connections between

the River Vision touchstones, habitat restoration, and effectiveness monitoring actions for the CTUIR Fisheries Habitat Program. We also thank Heather Bervid, Mackenzie Keith, Joseph Mangano, and Jackie Olson from USGS for their help preparing the manuscript. The CTUIR DNR and the U.S. Geological Survey Cooperative Matching Funds program supported this effort. Support for GCP's participation in development of this paper provided by the Montana Agricultural Experiment Station.
